

LDTRSH

Load Register Signed Halfword (unprivileged) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2*.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes*.

0	1	1	1	1	0	0	0	1	x	0	imm9									1	0	Rn				Rt					
size		opc																													

32-bit (opc == 11)

```
LDTRSH <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit (opc == 10)

```
LDTRSH <Xt>, [<Xn|SP>{, #<simm>}]
```

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```

integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp\_LOAD else MemOp\_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp\_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;

boolean tagchecked = memop != MemOp\_PREFETCH && (n != 31);

```

Operation

```

bits(64) address;
bits(16) data;

boolean privileged = AArch64.IsUnprivAccessPriv();
AccessDescriptor accdesc = CreateAccDescGPR(memop, FALSE, privileged, t);

if n == 31 then
    if memop != MemOp\_PREFETCH then CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = address + offset;

case memop of
    when MemOp\_STORE
        data = X[t, 16];
        Mem[address, 2, accdesc] = data;

    when MemOp\_LOAD
        data = Mem[address, 2, accdesc];
        if signed then
            X[t, regsize] = SignExtend(data, regsize);
        else
            X[t, regsize] = ZeroExtend(data, regsize);

    when MemOp\_PREFETCH
        Prefetch(address, t<4:0>);

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
